

**Istanbul Medipol University**  
**School of Engineering and Natural Sciences**  
**General Physics 1**

**Midterm**

**17 November 2019**

**Duration: 120 min**

Name	
Student ID	
Department	
Signature	

- Closed book, closed notes, no calculators
- Write your student ID on every page in the spaces provided above.
- Show all your work. Your work and answers must be shown on the pages provided. You may write on the back side of the paper.
- Your grade will be based on the correctness of your solution and the clarity of your work leading up to the solution.
- Numerical answers must be given with correct SI units, and SI unit symbols must be used only.

**Grade:**

Question	Course Learning Outcome	Grade
1 (20 points)	1, 3	
2 (20 points)	1, 3	
3 (20 points)	1, 3	
4 (20 points)	1, 3	
5 (20 points)	1, 3	
Total		

**Question 1 (from Young and Friedman)**

An automobile and a truck start from rest at the same instant, with the automobile initially at some distance behind the truck. The truck has a constant acceleration of  $2 \text{ m/s}^2$ , and the automobile an acceleration of  $3 \text{ m/s}^2$ . The automobile overtakes the truck after the truck has moved  $40 \text{ m}$ .

- a. How much time does it take the automobile to overtake the truck?
- b. How far was the automobile behind the truck initially?
- c. What is the speed of each when the automobile catches the truck?

**Question 2 (from Prof. Bordel)**

A helicopter has constant vertical speed  $v_h$  downwards. When the helicopter is at a height  $H$ , right below it there is a boat that is moving horizontally with speed  $v_d$ . If at this instant, a package is thrown from the helicopter horizontally:

- What should be the initial speed and direction (left or right) of the package with respect to the helicopter for it to land on the boat?
- How long does it take for the package to reach the boat?
- What is the trajectory  $y(x)$  of the package for an observer on the shore?
- What is the horizontal distance traveled by the package?
- When the package lands on the boat, which way does its velocity point? What is the angle between the velocity and the horizontal?

**Question 3 (from Prof. Chiao)**

Two masses  $m_1 = 5\text{ kg}$  and  $m_2 = 10\text{ kg}$  are on opposite sides of a double incline that has an angle of  $\theta = 30^\circ$  with respect to the ground on both sides. The masses are attached by a spring over a pulley that sits at the top of the incline. The spring and pulley are massless and the incline is frictionless. (You can take  $g = 10\text{ m/s}^2$ )

- Draw free body diagrams for both masses
- Find the acceleration of the two masses
- Find the tension in the string

**Question 4 (from Prof. Tonguc)**

A point object with mass  $m$  is tied to a vertical rod with two massless ropes as shown in the figure. If  $m$  is uniformly turning in the horizontal plane around the rod;

- Draw the free body diagram for  $m$  and write the relevant equations.
- Given the values listed below, find the tension  $T_1$  and the linear velocity of  $m$ .

$$T_2 = 50 \text{ N}$$

$$R = 2 \text{ m}$$

$$m = 8 \text{ kg}$$

$$g = 10 \text{ m/s}^2$$

$$\theta = 53^\circ$$

$$\sin 53^\circ = 0.8$$

$$\cos 53^\circ = 0.6$$

**Question 5 (from Prof. Bordel)**

A block of mass  $m$  is released from rest at the top of an incline forming an angle  $\theta$  with the horizontal. After traveling a distance  $L$ , the block hits a spring of stiffness constant  $k$  which is initially in its equilibrium configuration. The surface of the incline is rough above the spring - with a coefficient of kinetic friction  $\mu_k$  between the block and the ramp - but smooth under the spring as seen in Figure.

- Without any calculation, explain whether or not the block reaches the top of the incline after being pushed by the spring.
- Determine the speed of the block when it reaches the spring.
- Determine the length of the compression  $l$ .
- Determine the distance  $d$  traveled by the block on the way back, from the point where it loses contact with the spring to where it reaches its maximum height.
- Determine the kinetic friction coefficient that allows the block to get to a stop after traveling a distance  $L/2$  on the way back.
